Every tree with nvertices has n-1edges.

Kraft inequality: If the depths of the leaves of a binary tree are

$$d_1, \dots, d_n$$
:  

$$\sum_{i=1}^{n} 2^{-d_i} \le 1,$$

and equality holds only if every internal node has 2 sons.

## Recurrences

Master method:

$$T(n) = aT(n/b) + f(n), \quad a \ge 1, b > 1$$

If  $\exists \epsilon > 0$  such that  $f(n) = O(n^{\log_b a - \epsilon})$ 

$$T(n) = \Theta(n^{\log_b a}).$$

If 
$$f(n) = \Theta(n^{\log_b a})$$
 then  $T(n) = \Theta(n^{\log_b a} \log_2 n)$ .

If  $\exists \epsilon > 0$  such that  $f(n) = \Omega(n^{\log_b a + \epsilon})$ , and  $\exists c < 1$  such that  $af(n/b) \leq cf(n)$ for large n, then

$$T(n) = \Theta(f(n)).$$

Substitution (example): Consider the following recurrence

$$T_{i+1} = 2^{2^i} \cdot T_i^2, \quad T_1 = 2.$$

Note that  $T_i$  is always a power of two. Let  $t_i = \log_2 T_i$ . Then we have

$$t_{i+1} = 2^i + 2t_i, \quad t_1 = 1.$$

Let  $u_i = t_i/2^i$ . Dividing both sides of the previous equation by  $2^{i+1}$  we get

$$\frac{t_{i+1}}{2^{i+1}} = \frac{2^i}{2^{i+1}} + \frac{t_i}{2^i}.$$

Substituting we find

$$u_{i+1} = \frac{1}{2} + u_i, \qquad u_1 = \frac{1}{2},$$

which is simply  $u_i = i/2$ . So we find that  $T_i$  has the closed form  $T_i = 2^{i2^{i-1}}$ . Summing factors (example): Consider the following recurrence

$$T(n) = 3T(n/2) + n$$
,  $T(1) = 1$ .

Rewrite so that all terms involving Tare on the left side

$$T(n) - 3T(n/2) = n.$$

Now expand the recurrence, and choose a factor which makes the left side "telescope"

$$1(T(n) - 3T(n/2) = n)$$
$$3(T(n/2) - 3T(n/4) = n/2)$$

$$3^{\log_2 n - 1} (T(2) - 3T(1) = 2)$$

Let  $m = \log_2 n$ . Summing the left side we get  $T(n) - 3^m T(1) = T(n) - 3^m =$  $T(n) - n^k$  where  $k = \log_2 3 \approx 1.58496$ . Summing the right side we get

$$\sum_{i=0}^{m-1} \frac{n}{2^i} 3^i = n \sum_{i=0}^{m-1} \left(\frac{3}{2}\right)^i.$$

Let  $c = \frac{3}{2}$ . Then we have

$$n \sum_{i=0}^{m-1} c^i = n \left( \frac{c^m - 1}{c - 1} \right)$$

$$= 2n(c^{\log_2 n} - 1)$$

$$= 2n(c^{(k-1)\log_c n} - 1)$$

$$= 2n^k - 2n,$$

and so  $T(n) = 3n^k - 2n$ . Full history recurrences can often be changed to limited history ones (example): Consider

$$T_i = 1 + \sum_{j=0}^{i-1} T_j, \quad T_0 = 1.$$

Note that

$$T_{i+1} = 1 + \sum_{j=0}^{i} T_j.$$

Subtracting we find

$$T_{i+1} - T_i = 1 + \sum_{j=0}^{i} T_j - 1 - \sum_{j=0}^{i-1} T_j$$
  
=  $T_i$ .

And so 
$$T_{i+1} = 2T_i = 2^{i+1}$$
.

Generating functions:

- 1. Multiply both sides of the equation by  $x^i$ .
- 2. Sum both sides over all i for which the equation is valid.
- 3. Choose a generating function G(x). Usually  $G(x) = \sum_{i=0}^{\infty} x^i g_i$ .
- 3. Rewrite the equation in terms of the generating function G(x).
- 4. Solve for G(x).
- 5. The coefficient of  $x^i$  in G(x) is  $g_i$ . Example:

$$g_{i+1} = 2g_i + 1, \quad g_0 = 0.$$

Multiply and sum:  

$$\sum_{i>0} g_{i+1}x^i = \sum_{i>0} 2g_ix^i + \sum_{i>0} x^i.$$

We choose  $G(x) = \sum_{i>0} x^i g_i$ . Rewrite in terms of G(x):

$$\frac{G(x) - g_0}{x} = 2G(x) + \sum_{i \ge 0} x^i.$$

Simplify

$$\frac{G(x)}{x} = 2G(x) + \frac{1}{1-x}.$$

Solve for 
$$G(x)$$
: 
$$G(x) = \frac{x}{(1-x)(1-2x)}.$$

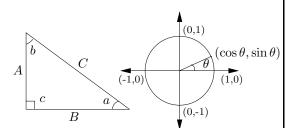

Expand this using partial fractions: 
$$G(x) = x \left(\frac{2}{1-2x} - \frac{1}{1-x}\right)$$
 
$$= x \left(2\sum_{i \geq 0} 2^i x^i - \sum_{i \geq 0} x^i\right)$$
 
$$= \sum_{i \geq 0} (2^{i+1} - 1)x^{i+1}.$$

So 
$$g_i = 2^i - 1$$
.
